Network Performance Monitor

The network performance monitor tool installed on the server helps in monitoring the network devices over the network by managing the routers, switches and all the snmp enabled devices. This tool helps in tracking the availability and health of the devices in the network. By using the network performance monitor we can find the root cause for the issue and resolve it before it causes the outage. It automatically discovers the new network devices and starts monitoring it immediately. The alerts can be setup and managed to monitor the snmp enabled devices over the network in the university. We can analyze the performance of the network devices and manage them effectively for better performance. We can categorize the nodes into groups and quickly identify where the issue is occurring.

The above tool installed in the university server helps a lot in analyzing the performance of the network and devices for a healthy and efficient network.
