Java derives much of its power from the many classes already defined in the Java Application Programming Interface (aka Java API). But how are we ever to learn and use these classes if we don’t know about them? Any textbook on Java can only begin to cover these classes and the methods defined in them. For a complete listing of these classes and methods you will need to visit the Java 6 API: http://docs.oracle.com/javase/6/docs/api/

Although the information covered in the textbook is sufficient to complete all of the programming and lab assignments for this course, you may find yourself wishing for a “better” class or method, or just more information on a known class or method. The Java™ Platform, Standard Edition, v 6.0 API Specification website (see link above) is the place to find that information!

All class definitions are found in the Java API Specifications. API stands for application programming interfaces and is more simply a set of existing “building blocks” for programmers to use to develop programs. The API is divided into packages. Packages contain classes. Classes contain methods. Methods contain Java code. We use methods in our Java programs.

Access the Java 6 API at the link above. Why is it abbreviated to Java SE (what does the SE stand for)?

__________________________________________________________________________

The API Specifications page is divided into 3 sections. The upper left-hand section is used to navigate to different packages (collections of classes). Below this section is a listing of all Java classes in alphabetical order. The largest section of the page displays details about a selected package or class. At present (before selecting a class or package), all Java packages are listed.

Scroll down the main display section of the page until you find the java.lang package. What does it provide?

__________________________________________________________________________

The java.lang package is automatically provided/imported for all Java programs. Find the java.util package. What does it provide?

__________________________________________________________________________
Clicking on any package will get a detailed description of the package. Click on `java.util`. This detailed description provides 6 summaries of items contained in this package. List the four summaries which are written in the blue background:

_________________________________________________________________________
_________________________________________________________________________
_________________________________________________________________________
_________________________________________________________________________

For now, we are interested in the **Class Summary**. This summary lists the classes that are contained in the package. The left column contains the name of the class. Notice that all class names start with a capital letter. The right column contains the description of the class. Scroll down until you find the **Scanner** class. What does it contain?

_________________________________________________________________________
_________________________________________________________________________

Click on the **Scanner** class. You will get a detailed description of what is contained in the **Scanner** class. Notice that the package name - `java.util` - appears (in small print) above the class name. Scroll down a few pages to see the two summaries available for the Scanner class. What are they?

_________________________________________________________________________
_________________________________________________________________________

Scroll down to the **Method Summary**. The left column indicates the type of information the method will return. The right column contains the method name (underlined), the parameters (in parentheses) and a brief description of the method.

Examine the first method listed for the Scanner class. It is the **close()** method. The left column contains `void`, indicating that this particular method does not return anything. All methods have a return type, even if the return type is simply `void`. The right column tell us the name of the method is `close` and the empty `()` indicates that this method does not require any parameters to be used. The name of the method is located immediately before the open parenthesis. All methods require parentheses.

Based on this information, you could invoke this method using the programming statement `scan.close();` where `scan` is an already declared and initialized **Scanner** object.

Let’s look at another **Scanner** method. Locate the method **findInLine()**. This method’s return type is a **String**. It requires 1 parameter in order to invoke this method. The parameter is of type **String** and its name is **pattern**. The definition tells us that this method “attempts to find the next occurrence of a pattern constructed from the specified string, ignoring delimiters.”
Java API Exercise

Based on this information, you could invoke this method using the programming statement:

```java
String result = scan.findInLine( "xx" );
```

where `scan` is an already declared and initialized Scanner object. The variable `result` will then reference the String produced/returned by the method.

Click on the name of the Scanner method `findInLine()`. This will provide you additional information about the method. Notice the line at the top of the page:

```java
public String findInLine( String pattern)
```

This line is known as the method header. This is what we see in two columns on the previous page with the added word `public`. The word `public` indicates that this method is “publically assessible” so that we can use it. The return type follows and is a String. A method only ever returns one type. The word located immediately before the parentheses is the name of the method. Everything listed inside of the parentheses are the parameter specifications.

Choose your browser’s back button to return to the Scanner class’s Method Summary. Let’s look at another class – the String class. To locate the String class, use the left hand alphabetically listing of classes. What package is the String class part of?

Under the String class Method Summary, locate the String method `trim()`. For this method, provide the following:

Method return type: ____________________________

Required parameters for the method: ____________________________

Purpose of the method: ____________________________

What would be displayed as a result of executing the following programming statements?

```java
String fname = "Ben", lname = "Franklin";
System.out.println( fname + lname);
System.out.println( fname.trim() + lname);
```

There are so many great methods to be used from the String class that you will surely return to this class’s API many times! But before you review more or the String methods, let’s take a look at a special type of class.
Java API Exercise

The Math class is a class that only contains static methods. First, locate the Math class. In which Java package can you find the Math class?

_________________________________________________________________________

Scroll down to the Method Summary section of the Math class. Examine the first method called abs(). The left column contains static double. The word double tells us that the return type of the method is double. But what does static mean? Static tells us that this method does not act on an object from the Math class but that we can just call this method whenever needed. First, answer these questions about abs():

Method return type:  

Required parameters for the method:  

Purpose of the method:  

Because abs() is a static method, to invoke the method you would use the class name and then the method. For example, executing System.out.println( Math.abs( 3-10 ) ); would result in 7.

Review the Math method ceil() and answer these questions:

Method return type:  

Required parameters for the method:  

Purpose of the method:  

Example of invoking the method:  

What have you learned?

• The Java API is divided into packages
• Packages contain classes
• Class names start with a capital letter
• Classes contain methods
• The name of the method is directly to the left of the open parenthesis
• All methods require parenthesis
• Parameters are specified with a type followed by an identifier
• All methods have a return type
• The return type of the method is located directly to the left of the method name
