Lab 12  

Name:_________________________  Checked:_____

Objectives:
More practice using two dimensional arrays to process values of different types.

Preparation
Review the code and modify it as described below.

```
public class TwoDArray {
   // Creates a 2D array of integers, fills it with increasing
   // integer values, then prints them out.
   public static void main (String[] args) {
      int[][] table = new int[5][10];
      // Load the table with values
      for (int row=0; row < table.length; row++)
         for (int col=0; col < table[row].length; col++)
            table[row][col] = row * 10 + col;
      // Print the table
      for (int row=0; row < table.length; row++)
         for (int col=0; col < table[row].length; col++)
            System.out.print (table[row][col] + " ");
      System.out.println();
   }
}
```

1. Run this program and observe what it does.
2. The output produced is shown below. Circle the entries for table[0][5] and for table[3][2]

```
<table>
<thead>
<tr>
<th></th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
<th>9</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>10</td>
<td>11</td>
<td>12</td>
<td>13</td>
<td>14</td>
<td>15</td>
<td>16</td>
<td>17</td>
<td>18</td>
<td>19</td>
</tr>
<tr>
<td>1</td>
<td>20</td>
<td>21</td>
<td>22</td>
<td>23</td>
<td>24</td>
<td>25</td>
<td>26</td>
<td>27</td>
<td>28</td>
<td>29</td>
</tr>
<tr>
<td>2</td>
<td>30</td>
<td>31</td>
<td>32</td>
<td>33</td>
<td>34</td>
<td>35</td>
<td>36</td>
<td>37</td>
<td>38</td>
<td>39</td>
</tr>
<tr>
<td>3</td>
<td>40</td>
<td>41</td>
<td>42</td>
<td>43</td>
<td>44</td>
<td>45</td>
<td>46</td>
<td>47</td>
<td>48</td>
<td>49</td>
</tr>
</tbody>
</table>
```

3. Modify the program so that the output rows and columns are labeled. The output should now look EXACTLY like this:

```
# | 0  | 1  | 2  | 3  | 4  | 5  | 6  | 7  | 8  | 9  |
---|----|----|----|----|----|----|----|----|----|----|
0  |    |    |    |    |    |    |    |    |    |    |
1  | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 |
2  | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 |
3  | 30 | 31 | 32 | 33 | 34 | 35 | 36 | 37 | 38 | 39 |
4  | 40 | 41 | 42 | 43 | 44 | 45 | 46 | 47 | 48 | 49 |
```

4. Modify the dimensions of the array – make it 3 rows by 4 columns and run the program again. The output should still look OK without having to change anything else in the program. If necessary, adapt your program so that it works with any reasonable dimensions (note that there is a limit to how many columns can be displayed across on one line, so it is not expected to work well with large values for the number of columns).

Submit your updated version of TwoDArray.java through Blackboard by 8:00am the morning of the Lab.

A. 2D array of double

1. Make a new version of your program from part A that creates an 2D array of 5x5 values of type double, set to random values in the range 0….1 (use Math.random()).

2. Examine your code: you should still have two nested loops (one to initialize the 2D array and one to print its contents). Add a third nested loop to process the array entries one more time, this time counting how many are greater than 0.5 (since the entries were generated randomly, it should be about half of them), and some code to display the count. Run the program a few times to note the counts below:

__________ _______ _______ _______ _______ _______ _______ _______ _______ _______

3. Increase the array size to a 100x100 and comment out or delete the code that outputs the array (ie, we want to avoid huge amount of output – we are only interested in the number of elements greater than 0.5, at this point). Run the program a few more times and note the counts again:

__________ _______ _______ _______ _______ _______ _______ _______ _______ _______

4. Incorporate a timer in your program. How much longer does it take to run for different size arrays? You can try 200x200, 300x300, 500x500, 1000x1000, etc and observe the times in milliseconds.

Array size: _______ _______ _______ _______ _______ _______ _______ _______ _______ _______

Milliseconds: _______ _______ _______ _______ _______ _______ _______ _______ _______ _______

B. 2D array of boolean

1. Make a new version of your program that creates a 2D array of 5x5 values of type boolean. Use an initializer list to instatiate and initialize the array table to represent the following configuration, where the asterisk indicates a true value at that position in the array (no asterisk means false). For example, table[1][3] is false, whereas table[2][1] is true.

<table>
<thead>
<tr>
<th>#</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>*</td>
<td>*</td>
<td>*</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>*</td>
<td>*</td>
<td>*</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>*</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>*</td>
<td>*</td>
<td>*</td>
<td></td>
</tr>
</tbody>
</table>

2. Suppose indices represent people and that the value at row i, column j of this 2D array is true just in case i likes j, and false otherwise. For example, person 3 likes persons 1 and 2, but does not like person 3(self). Write some code to output all the matches contained in the array; a match means that person x likes person y and vice-versa. In the above example we have two matches: (0,1) and (1,2).

3. (Optional) Experiment with a large array of this kind representing a large number of users, setting the values randomly and exploring the number of matches obtained.
